

# Generalising Invariant Coordinate Selection to a non-linear dimensionality reduction method

Master Thesis Defence for Econometrics and Management Science  
Business Analytics & Quantitative Marketing  
By Christopher Claassen

# Contents

- Dimensions and orthogonality
- Dimensionality reduction methods
- Non-linear extensions via kernels
- Empirical applications of kernelised Invariant Coordinate Selection (ICS)
- Challenges and directions for future works

# Setting the stage: what are dimensions?

- Dimensions are that what is required for describing everything residing in a space
  - > For example, the three physical dimensions (forwards, sideways and upwards) determine our position in this room
- Hyperspaces also exist and contain higher dimensional objects
  - > Finding a good representation in lower dimensions is challenging

From measurements

to

data matrices

Each type of measurement becomes a column, the number of columns gives the dimensionality

Sepal length ♦	Sepal width ♦	Petal length ♦	Petal width ♦
5.1	3.5	1.4	0.2
4.9	3.0	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5.0	3.6	1.4	0.3
5.4	3.9	1.7	0.4
4.6	3.4	1.4	0.3
5.0	3.4	1.5	0.2
4.4	2.9	1.4	0.2
4.9	3.1	1.5	0.1

# Ideal dimensions versus reality

- Ideally, we would like for dimensions to be **orthogonal**
  - > This means we can move along one dimension without changing another
- In practice, measurements are often **correlated** and thus **not orthogonal**
  - > For the same flower species, observing a taller petal corresponds to a wider petal
- Nevertheless, we can often reorient the data such that it becomes orthogonal
  - > This turns out to be very useful for dimensionality reduction

# Dimensionality reduction

- Dimensionality reduction entails using less dimensions than observed
- Possible advantages:
  - > Quicker computations
  - > Can reduce noise in the data
- Possible disadvantages:
  - > Requires additional computations
  - > Loss of relevant information
- Often done as a preprocessing step for subsequent statistical analysis

# Principal Component Analysis (PCA)

- PCA is a method that reorients the data such that it becomes orthogonal
  - > In practice, this means rotating and stretching the data
- PCA achieves this by exploiting the variance-covariance structure of the data
  - > Variance: measures the spread of a dimension
  - > Covariance: measures the joint variation of two dimensions
- Dimensionality reduction is achieved by discarding dimensions with little variance
  - > A dimension that varies little is often uninteresting in practice

# From covariances to scatters

*Erasmus*

# Invariant Coordinate Selection (ICS)

- ICS generalises PCA, as it uses 2 different scatters rather than 1
  - > The two scatters cannot be the same, there must be some form of contrast
- The two scatters jointly determine the type of structure uncovered
  - > For example, using covariance versus robust covariance can reveal outliers
- The structure ICS finds is often on a low-dimensional subspace
- The challenge for using ICS is finding the appropriate scatters

(1000 observations in 2 dimensions over 3 groups)

*Erasmus*

# Addressing non-linearity via kernels

- Non-linearity cannot be tackled via rotating and stretching the data
- Kernels capture a certain 'core' of non-linearity of the data
  - > Kernels can replace the role of scatters in ICS
- We focus on two types of kernels: reproducing kernels and smoothing kernels
- Reproducing kernels capture non-linear functions of the data
- Smoothing kernels capture the interaction between a point and its close neighbours

# Empirical applications of kernelised ICS

- Dimension reduction via kernelised ICS is able to uncover specific types of structure
  - > In particular, specific types of non-linear structure
- There are many possible subsequent statistical applications, such as:
  - > Data visualisation
  - > Detecting data anomalies
  - > Finding clusters of similar observations in the data
- Using non-linear methods directly for these applications is costlier

# Empirical application of ICS: Wine data

- The dataset consists of wine samples originating from different cultivars
- There are 129 samples with 13 chemical measurements each
  - > Examples of measurements are alcohol contents, sweetness and hue
- The goal is to distinguish between two different cultivars using only few dimensions
  - > For the dimensionality reduction step, we do not use the labels
- Other applications that can use this methodology include:
  - > Detecting counterfeit objects
  - > Finding defective machine parts

# Empirical application of ICS : Word embedding data

- The dataset consists of word embedding created by machine learning models
- There are 11 classes spread over 601 words with 300 dimensions each
  - > The dimensions do not have a direct interpretation
- The goal is to visualise the different word clusters by transferring the information of only a few dimensions to a different method called t-SNE
  - > For the dimensionality reduction step, we do not use the class labels
- Other applications of this type of data include:
  - > Processing written customer reviews
  - > Creating AI chatbots like ChatGPT

# Empirical application of ICS : Word embedding data

# Challenges and directions for future works

- We have seen that ICS with kernels can be successfully applied as a dimensionality reduction method for a variety of applications, but this was not without challenges:
  - > Creating a computer package that effectively performs kernelised ICS
  - > Determining which kernel pairs to use
  - > Accounting for numerical instability caused by using kernels
- There is also still potential for improvement of ICS with kernels:
  - > Studying theoretical aspects
  - > Component selection
  - > Kernel hyperparameter optimisation
